Open the browser, search for a product, scan the entire range, click, swipe, and smile!

Without batting an eyelid, we can purchase the latest model of mobile phones and electronic gadgets, or contemporary furniture or home accessories, just snapping our fingers. The e-commerce sites customize their range of offerings, as per our budget, needs, and tastes. And the happy customer will surely knock again in the future, and even recommend the site on his social circuit. So, every e-commerce site or content provider endeavors to enhance the online shopping experience, to attract and retain customers, bag higher ratings and positive reviews, and stay ahead of the competition. For this purpose, they engine.

Matrix factorization is one of the most sought-after algorithms for recommendation systems, enabling the system to gauge the customer's preferences, rank the right product or service, and recommend items based on their requirement, the lead translates into a transaction.

What is Matrix Factorization

This mathematical model helps the system split a large rectangular array of numbers or functions, to display recommendations to users and items.

Where is Matrix Factorization

Once an individual raises a query on a search engine, the system outputs in the form of recommendations. The system

filtering- to make recommendations.

Content-Based Filtering

This approach recommends items based on user preferences. It matches the requirement, considering the past actions of the user, patterns detected, or any explicit feedback provided by the user, and accordingly, makes a recommendation.

Example: If you prefer the chocolate flavor and purchase a chocolate ice cream, the next time you raise a query, the system shall scan for options related to chocolate, and then, recommend you to try a chocolate cake.

How does the System make recommendations?

Let us take an example. To purchase a car, in addition to the brand name, people check for features available in the car, most common ones being safety, mileage, or aesthetic value. Few buyers consider the automatic gearbox, while others opt for a combination of two or more features. To understand this concept, let us consider a two-dimensional vector with the features of safety and mileage.

| | Car features | | | |
|---------|--------------|-------|-------|-------|
| | Car A | Car B | Car C | Car D |
| Safety | 4 | 1 | 2 | 1 |
| Mileage | 1 | 4 | 2 | 2 |

| Individual preferences | Safety | Mileage |
|------------------------|--------|---------|
| Person A | 1 | 0 |
| Person B | 0 | 1 |
| Person C | 1 | 0 |
| Person D | 1 | 1 |

1. In the above graph, on the left-hand side, we provide a rating on safety and mileage. If the i that particular feature, we assign 0. Now we c Person D opts for both Safety and Mileage.
2. Cars are been rated based on the number of f fewer features.
 - A ranks high on safety and low on mileage
 - B is rated high on mileage and low on safety
 - C has an average rating and offers both safe
 - D is low on both mileage and safety
3. The blue colored ? mark is the sparse value, w consideration list for buying the car or has forc
4. Let's understand how the matrix at the center individuals. Person A has given an overall ratin

Job Gurantee Courses

through the following calculations-

- For Car A = (1 of safety preference x 4 of safety features) + (0 of mileage preference x 1 of mileage feature) = 4;
- For Car B = (1 of safety preference x 1 of safety features) + (0 of mileage preference x 4 of mileage feature) = 1;
- For Car C = (1 of safety preference x 2 of safety features) + (0 of mileage preference x 2 of mileage feature) = 2;
- For Car D = (1 of safety preference x 1 of safety features) + (0 of mileage preference x 2 of mileage feature) = 1

Now on the basis of the above calculations, we can predict the overall rating for each person and all the cars.

If person C is asking the search engine to recommend options available for cars, basis the content available, and his preference, the machine will compute the table below:

- It will rank cars based on overall rating.
- It will recommend car A, followed by car C.

Mathematics behind the recommendations made using content-based filtering

In the above example, we had two matrices, that is, individual preferences and car features, and 4 observations to enable the comparison. Now, if there are ' n ' number of observations in both matrix **a** and **b**, then-

- **Dot Product**

The dot product of two length- n vectors **a** and **b** are defined as:

The dot product is only defined for vectors of the same length. In the above example, we had 4 observations.

- **Cosine**

There are alternative approaches or algorithms to calculate the cosine similarities. It is used to determine the nearest neighbors. A search engine can make such a recommendation based on the cosine similarity between two vectors **a** and **b** is, in fact,

Job Gurantee Courses

By applying the definition of similarity, this will equal 1 if the two vectors are identical, and it will be 0, if the two are orthogonal. In other words, similarity is a number ranging from 0 to 1 and tells us the extent of similarity between the two vectors. Closer to 1 is highly similar and closer to 0 is dissimilar.

- **TF-IDF (Term frequency and Inverse document frequency)**

Let us assume the matrix only has text or character elements, then the search engine uses TF-IDF algorithm to find similarities and make recommendations. Each word or term has its respective TF and IDF score. The product of the TF and IDF scores of a term is called the TF-IDF weight of that term.

The TF (term frequency) of a word is the number of times it appears in a document. When you know it, you can find out if a term is being used too often or too rarely.

The IDF (inverse document frequency) of a word is the measure of how significant that term is in the whole corpus.

The higher the TF-IDF score (weight), more important the word is.

Advantages of content-based filtering

The model does not require any data about other users, which makes it easier to scale it up to a large number of users.

a) The model can capture specific interests of content items, even if very few other users are interested in them.

Disadvantages of content-based filtering

a) Since the feature representation of the items is based on domain knowledge. Therefore, the model can only recommend items that are similar to the ones the user has interacted with.

b) The model can only make recommendations based on the user's limited ability to expand on the users' existing interests.

Collaborative Filtering

This approach uses similarities between users and items simultaneously, to provide recommendations. It is the idea of recommending an item or making a prediction, depending on other like-minded individuals. It could comprise a set of users, items, opinions about an item, ratings, reviews, or purchases.

Example: Suppose Persons A and B both like the chocolate flavor and have them have tried the ice-cream and cake, then if Person A buys chocolate biscuits, the system will recommend chocolate biscuits to Person B.

Types of collaborative filtering

Collaborative filtering is classified under the memory-based and model-based approaches:

How does system make recommendations

In collaborative filtering, we do not have the rating or overall rating, given by the individuals for each item. We do not know about the car or is not under the consideration.

Job Gurantee Courses

The task in hand is to predict the rating that Person C might assign to Car C (? marked in yellow) basis the similarities in ratings given by other individuals. There are three steps involved to arrive at a collaborative filtering recommendation.

Step-1

Normalization: Usually while assigning a rating, individuals tend to give either a high rating or a low rating, across all parameters. Normalization usually helps in balancing and evens out such measures. This is done by taking an average of rating available and subtracting it with the individual rating ($x - \bar{x}$)

a) In case of Person A = $(4+1+2+1)/4 = 2 = \bar{x}$, In case of Person B = $(1+4+2)/3 = 2.3 = \bar{x}$

Similarly, we can do it for Persons C and D.

b) Then we subtract the average with individual rating

In case of Person A it is, 4-2, 1-2, 2-2, 1-2, In case for Person B = 1-2.3, 4-2.3, 2-2.3

Similarly, we can do it for Persons C and D.

You get the below table for all the individuals.

If you add all the numbers in each row, then it will come to zero. From zero, if individual rating for each car is subtracted, it does not like the car.

Step-2

Similarity measure: As discussed in content-based filtering, it is the ratio between their dot product and the product of their norms.

- > **Placement opportunities with top companies**

Job Gurantee Courses

Step-3

Neighborhood selection: Here in Car C column, we find maximum similarities between ratings assigned by Persons A and D. We use these similarities to arrive at the prediction.

Mathematics behind recommendations made using collaborative filtering

In this approach, similarities between pair of items are computed using cosine similarity metric. The rating for target item ' i ' for an active user ' a ' can be predicted by using a simple weighted average as:

where k is the neighborhood of most similar items rated by active user a , and $w(i,j)$ is the similarity between items i and j .

Advantages of collaborative filtering

- There is no dependence on domain knowledge
- The model can help users discover new interests
- To some extent, the system needs only the feedback

Disadvantages of collaborative filtering

- The matrix cannot handle fresh items, for instance
- The output of the recommendation could be biased

So, this was all about matrix factorization, the algorithms used to search information
